

Diagramatix — Quick Reminder Sheet 12

AI Generation for Domain Diagrams

Diagramatix can build a Domain (UML class) diagram two ways: from a written description of the domain, or by **reproducing an uploaded image** of an existing class diagram. Both open from the AI panel, which also supports saved prompts, dictation, and attachments.

FROM A DESCRIPTION

Type what the domain contains — the entities, their attributes, and how they relate — and press **Generate**. The model returns the entities and relationships, and Diagramatix lays them out on the canvas. The generator understands the full domain vocabulary:

- **Elements:** entities (classes), enumerations, packages, and notes (plus pain-point markers).
- **Relationships:** association, aggregation, composition, generalisation, dependency, realisation, containment, and note-anchor.
- It applies UML rules for abstract classes, multiplicities, role names vs. association names, navigability, and arrow direction automatically.

FROM AN IMAGE (IMAGE INGESTION)

This is the fastest way to digitise an existing diagram:

- Use **Attach** to add an image of a UML class diagram — a photo, screenshot, or export (PNG, JPEG, WebP, or GIF, up to 10 MB).
- The panel auto-fills a “reproduce the attached diagram exactly” prompt. The image is sent to the model as a vision input, which reads (OCRs) the classes, attributes, operations, and connectors and treats the picture as the source of truth.

LAYOUT PRESERVATION

Rather than re-flowing the diagram onto a grid, the model reports each element’s **position and size as fractions of the image**, plus package nesting and which side each connector attaches to. Diagramatix rebuilds the diagram keeping the **original proportions and arrangement**, so the result looks like the picture you supplied. Association-end roles default to public +, and constraint boxes are placed outboard of the roles and multiplicities.

MODELS

Domain generation uses the same default model as the rest of the app — **Haiku 4.5** — overridable by the SuperAdmin AI-model setting.

Tip: After an image import, check role visibility and multiplicities against the original — the model reads them well, but a quick pass catches anything faint in the source image.
